

This publication features the results from MPGA sponsored trials.

Contents of this publication can only be reproduced with the permission of MPGA.

The evaluation of pulse varieties across five different pulse crop types (peas, lentils, faba beans, edible beans and soybeans) found within this publication is made possible by your continued support through your MPGA check-off levy. Financial assistance was also received from the Agri-Food Research and Development Initiatives (ARDI) and the Agriculture and Agri-food Canada (AAFC) Pulse Science Cluster fund.

TRIAL LOCATION AND DESIGN

The evaluation of dry beans was conducted at three locations (Morden, Carman and Portage la Prairie), under wide row (60 cm) conditions. At each location, the cultivars were repeated three times. There were 39 entries in the evaluation, separated into small- (navy, black), medium- (pinto, yellow) and large-seeded (cranberry, light red and dark red kidney).

IS ONE VARIETY BETTER THAN ANOTHER?

Look at the CV (Coefficient of Variation) and LSD (Least Significant Difference) that are printed within each trial. Coefficient of Variation is a measurement describing the amount of variation caused by factors unrelated to cultivars, such as non-uniform field spots, loss of plants, various water and fertilizer conditions, human errors, etc. Lower CVs (less than 15%) indicate a more uniform trial that will demonstrate the true differences between varieties. For all wide row edible bean trials the LSD represents the amount of beans (in lb/acre) that two varieties must differ before you can say with 95% certainty that a difference exists for those varieties in the same trial. For example, let's say an edible bean trial has an overall mean yield of 2944 lb/acre, a CV of 6%, and LSD of 301 lb/acre, the low CV indicates the trial has very few experimental errors and the LSD indicates variety yields varying by more than 301 lb/acre are truly different. You will notice that in the 2013 trials, yields

for the various sites are listed in one table. You will also note yield was not reported for each location and for each type. Due to the trial CV being greater than 15% and in some cases closer to 20%, it was determined that the yield data was too variable to publish. As stated previously, data with low CV's are preferred because a low CV indicates the trial has very few experimental errors.

In each table, **check varieties are bolded** for easier comparison with other varieties. The best way to determine the suitability of a variety in your area is to see how it pairs with the checks, and in as many different settings and years as possible. Some new cultivars or advanced breeding lines are included in the 2013 evaluation, but most entries have been tested in multiple years.

SOYBEAN VARIETY DESCRIPTION TABLE

You will note there are two new columns added to the soybean tables in 2013. The first is Maturity Grouping. Going forward, we will be using these ratings instead of Company heat units. This grouping is still a company rating but follows what is being done in other areas such as North Dakota and Ontario. The following is a brief explanation of how it works:

In Manitoba, we are growing varieties that range from 000 to 00.9 (triple-zero or double-zero varieties). Triple-zero would be the earliest and 00.9 would

be the latest you would want to grow in Manitoba, and only in long-season areas. A 00.4, 00.5, 00.6 would be best suited for mid-season zones, a 000, 00.1, 00.2, 00.3 would be suited for short-season regions and varieties from 00.7 to 00.9 would be suited to longer-season regions of Manitoba. If you are looking at varieties from a different area with a rating of 0.1, then that variety would be longer maturity than the latest variety that should be grown in Manitoba at 00.9. Keep in mind these are still companies' ratings. Relative days are taken every year and compared to a known check. These ratings are a reflection of the current season's growing conditions and can vary from year to year.

There is also a column for notes that is located in the soybean variety description table. These notes will indicate if a variety has any special features, such as Soybean Cyst Nematode resistance or Race resistance to Phytophthora root rot. These columns will continue to develop as more information is gathered. 

We acknowledge the hard work of all the people who plant, maintain, take notes, harvest the plots, and are responsible for the data contained within this publication. We appreciate the hard work of the staff at Agriculture and Agri-Food Canada, Morden Research Station the WADO, PCDF, PESAI and CMCDC research facilities and the private research companies, without whom this publication would not have been possible.

SEED AND HARVEST DATES – EDIBLE BEAN TRIALS

	Seeding Date	Harvest Date
Wide Row Edible Bean – Morden	June 11	September 25
Wide Row Edible Bean – Carman	May 29	October 1
Wide Row Edible Bean – Portage	June 6	October 16
Narrow Row Edible Bean – Carberry	May 22	October 7
Narrow Row Edible Bean – Thornhill	June 11	October 9
Narrow Row Edible Bean – Roblin	May 29	September 17

SOYBEAN DATES ARE LISTED WITHIN TABLES

KEY – APPLICABLE TO ALL EDIBLE BEAN CHARTS

Agronomic Traits		Disease Traits
Yield	lb/acre	Field Rating: Bacterial Blight Severity (0–5) 0 = No observable lesions or other signs of infection 1 = < 5% of plant area (leaf and stem-hypocotyls) diseased 2 = 5–10% of plant area diseased 3 = 10–25% of plant area diseased 4 = 25–50% of plant area diseased 5 = 50–100% of plant area diseased or death of seedling Bacterial Blight Incidence – % leaf tissue infected Anthraxnose Incidence – % plant tissue infected Rust Incidence – % plant tissue infected White Mould Incidence – % plant tissue infected
Maturity	Number of days to when 90% of plants ready to combine	
Plant Type (1–3)	1 = Determinate bush 2 = Indeterminate bush, erect stem and branches 2a: Without guides 2b: With guides and ability to climb 3 = Indeterminate bush with weak and prostrate stem and branches 3a: Short guides with no ability to climb 3b: Long guides with ability to climb	
Plant Height	Plant height in cm, rated at flowering	
Lodging (1–5)	Rated at maturity 1 = upright 5 = flat on the ground	
Pod Ht (> 5 cm)	% of pods above 5 cm from the ground	
Seed Weight	Grams per 1000 seeds	
Seed Quality (1–5)	Based on size, shape, colour and wrinkle-free seed coat 1 = very good 5 = very poor	

KEY – APPLICABLE TO ALL CHARTS

CV	Coefficient of Variation. The statistical measure of random variation in a trial. CV less than 15% generally indicates more uniform trial and conclusive data.
LSD	Least Significant Difference. The amount that two varieties must differ before it can be said with a 95% chance of certainty that a true difference exists.

2013 WIDE ROW SCREENING TRIAL – YIELDS

Yield was not reported for each location and for each type. Due to the trial CV being greater than 15% and in some cases closer to 20%, it was determined that the yield data was too variable to publish.

NATTO SOYBEANS – REPRINT FROM 2012

OAC Prudence is **not a natto type soybean**; it is used as a check to determine the yield potential of natto type soybeans compared to conventional soybeans.

¹ Maturity based on data from Carberry and Melita.

Not all varieties reached 95% brown pod in Roblin and Hamiota before first frost.

NOTES — APPLICABLE TO ROUNDUP READY AND CONVENTIONAL SOYBEAN CHARTS ONLY

MATURITY NOTES – always use more than one criteria to gauge maturity

- 1 Soybean varieties have been organized into three maturity zones – short-, mid- and long-season areas. Although there are no variety restrictions, the **short-season** grouping is meant to be a starting point for new growers in the outer production areas. The **long-season** group is targeted for southern Manitoba generally south of highway 23, with the **mid-season** grouping making up the bulk of the production area between the short- and long-season area.
- 2 Company Crop Heat Unit ratings are assigned to assist growers in selecting varieties suitable for their area. Unfortunately Company Heat Unit ratings do not always reflect the actual maturity in Manitoba. Growers should never rely on just one criteria for judging maturity. Experimental lines are not assigned a HU rating until they become registered.
- 3 Maturity grouping is a ranking of maturity provided by seed suppliers. These rankings are assigned to varieties to assist growers to select varieties suited for their area. For future years, maturity grouping will be used instead of CHU Ranking.
- 4 Relative days to maturity (dtm) is the number of days from seeding to plant maturity (95% of the pods on the plant are mature with seeds rattling in the pods when plant is shaken) and is expressed as + or - days from the check. Growers need to be cautious when using only one-year data when evaluating maturity and yield. Using multiple-year maturity data when available will give you a better indication on how a variety will mature with different growing seasons. Actual days to maturity for the check is found in the grey check box at the bottom of the table.

GENERAL NOTES

- 1 Roundup Ready, Conventional and soybean varieties are evaluated separately from Roundup Ready type varieties, meaning direct comparison of varieties between different tables is not possible. All trials are solid seeded at 210,000 plants/acre.
- 2 Hilum colour can range from Clear (CL), Yellow (Y), Imperfect Yellow (IY), Grey (GR), Brown (BR), Light Brown (LBR), Buff (BF), Imperfect Buff (IB) or Black (BL) and is solely a marketing issue. The hilum is the point on the soybean seed where it attaches to the pod.
- 3 Relative Seeds/lb – these were the seed numbers of the varieties entered into the trial. Soybean seed size can vary greatly between varieties and even from seed lot to seed lot of the same variety. Growers should use the seed size for their seed lot when calculating seeding rates.
- 4 Lodging is rated at harvest; 1=standing upright, 5=flat along the ground. A rating of 3 or more can promote white mould within the crop canopy.
- 5 Iron Deficiency Chlorosis (IDC) rating scores 1=green leaves, 2=yellowish leaves, 3=green veins with yellow leaves, 4=brown dead tissue between green veins, 5=severe chlorosis and a stunted growing point. Ratings were taken from one site prone to iron chlorosis over the last two years. IDC tolerant varieties are varieties with lower IDC scores and perform better on soils prone to iron deficiency chlorosis.
- 6 Iron Deficiency Chlorosis (IDC) grouping is used because varieties will have different visual rating scores from year to year. Numerical ratings, which are close but are in different groupings, will show similar symptoms. Both numerical and groupings should be considered together when judging IDC. Tolerant=leaves stayed green, Semi Tolerant=leaves when yellow then turned green, Susceptible=leaves went chlorotic and had dead patches on their leaves and were often stunted.

GRAND MEAN		66											
LSD (0.05)		4											

¹ Green seed coats: G = 0–10%; F = 11–25%

² Varieties which show good disease tolerance to one strain of Fusarium wilt may be susceptible to other strains.

³ Seed coat dimpling rating: VG = 0–5%; G = 6–20%; F = 21–50%

*The relative maturity of the variety Cutlass is 99 days (Medium). Please add 3–4 days for each rating beyond Medium. The relative vine length for Cutlass is 34-inches (Medium).

¹Traditionally tannin faba bean tan-coloured seed coats contain tannins and can't be fed directly to livestock. Zero tannin faba beans have white seed coats.

LENTILS

The Lentil variety trial is coordinated with the Saskatchewan Regional Variety testing program, therefore the seed source are same as used in Saskatchewan trials.

The lentil variety trial was tested by MCVET and partially sponsored by the Manitoba Pulse Growers Association.

Clearfield lentils are tolerant to the herbicide Odyssey. These varieties are easily identified by the "CL" designation at the end of the name.
