

Pulse Variety Evaluation in 2010

This publication features the results from MPGA sponsored trials.

Contents of this publication can only be reproduced with the permission of MPGA.

The evaluation of pulse varieties across five different pulse crop types (peas, lentils, fababeans, edible beans and soybeans) found within this publication are made possible with your continued support through your MPGA check-off levy. Financial assistance was also provided by the Agri-Food Research and Development Initiatives (ARDI) and the Agriculture and Agri-Food Canada (AAFC) Pulse Science Cluster fund.

Variety Evaluation Trial Notes

2010 was a year many Western Canadian farmers would prefer not to repeat – ever. It was also a tough year for the MPGA edible bean trials. Only one of the five regional Narrow Row Dry Bean trials (Thornhill site) was harvested; the rest were disc'd down. The Wide Row Dry Bean Screening trials fared a little better, with a full data set from Carman and most of the data from Winkler. Due to the excess moisture and damage to our Morden and Portage sites, we have decided not to publish the data.

Weather also was a factor in our other trials. The lentil and fababean trials received excess water and resulted in only one trial of each plot being valid.

The Carman Roundup Ready Soybean trial was also lost due to white mould and the Arborg pea trial was lost due to excess water.

How to Interpret the Data Tables

In the edible bean tables, the check variety for each bean class is displayed in **bold type**, and the yields (for the current year only) are all shown in lbs/acre. The best way to determine the suitability of a variety in your area is to see it in pairs with the checks, and in as many different settings and even years as possible.

For all other pulse crops, the check is identified in the check variety box at the bottom of the table. The variety yield data is shown as % of the check and the site years tested column is located beside the yield. The actual yield of the check is indicated in the check variety box at the bottom of the trial data.

Is one variety better than another?

In order to tell if there truly is a difference between varieties in a small plot variety trial, you need to review the figures at the bottom of the table. First, look at the CV% (Coefficient of Variation). The Coefficient of Variation is expressed as a % and is a

common measurement to describe how reliable the data in the trial is. In general, the lower the CV% the better quality the data in the trial is. The second piece of information to take note of is the LSD (Least Significant Difference). This number represents the amount of yield (in lbs/acre) that two varieties have to differ before you can say with 95% confidence that the yield potential between the true varieties is truly different.

In the Carman wide row small bean trial (on page 4) the 5% trial CV indicates the trial was very uniform, the LSD means that two Navy Bean varieties have to vary by more than 123 lbs/acre before they can be considered different.

We acknowledge the hard work of all the people who plant, maintain, take notes, harvest the plots, and are responsible for the data contained within this publication. We appreciate the hard work of the staff at the Agriculture and Agri-Food Canada, Morden Research Station, the WADO, PCDF, PESAI and CMCDC research facilities and the private research companies, without whom this publication would not have been possible. 🌱

KEY – APPLICABLE TO ALL EDIBLE BEAN CHARTS

Agronomic Traits		Disease Traits
Yield	lb/acre	Field Rating:
Maturity	Number of days to when 90% of plants ready to combine	Bacterial Blight Severity (0-5)
Plant Type (1-3)	1 = Determinate bush 2 = Indeterminate bush, erect stem and branches 2a: Without guides 2b: With guides and ability to climb 3 = Indeterminate bush with weak and prostrate stem and branches 3a: Short guides with no ability to climb 3b: Long guides with ability to climb	0 = No observable lesions or other signs of infection 1 = < 5% of plant area (leaf and stem-hypocotyls) diseased 2 = 5-10% of plant area diseased 3 = 10-25% of plant area diseased 4 = 25-50% of plant area diseased 5 = 50-100% of plant area diseased or death of seedling
Plant Height	Plant height in cm, rated at maturity	Bacterial Blight Incidence – % leaf tissue infected
Lodging (1-5)	Rated at maturity 1 = upright 5 = flat on the ground	Anthraco-nose Incidence – % plant tissue infected
Pod Ht (> 5 cm)	% of pods above 5 cm from the ground	Rust Incidence – % plant tissue infected
Seed Weight	Grams per 1000 seeds	White Mould Incidence – % plant tissue infected
Seed Quality (1-5)	Based on size, shape, colour and wrinkle-free seed coat 1 = very good 5 = very poor	

KEY – APPLICABLE TO ALL CHARTS

CV	Coefficient of Variation. The statistical measure of random variation in a trial. CV less than 15% generally indicates more uniform trial and conclusive data.
LSD	Least Significant Difference. The amount that two varieties must differ before it can be said with a 95% chance of certainty that a true difference exists.

¹ Traditional tannin fababeans have tan coloured seed coats that contain tannins and can't be fed directly to livestock. Zero tannin fababeans have white seed coats and can be fed directly to livestock.

LENTILS

Clearfield lentils are tolerant to the herbicide Odyssey. These varieties are easily identified by the “CL” designation at the end of the name.

* Maturity ratings from Boissevain, Wawanesa and Melita sites.

** Lodging ratings from Boissevain.

*** Varieties did not fully mature at Carberry, Hamiota and Roblin. No varieties fully matured at Roblin.

^ Indicates Genuity Roundup Ready 2 Yield™ soybean variety.

NOTES – APPLICABLE TO ROUNDUP READY AND CONVENTIONAL SOYBEAN CHARTS ONLY

MATURITY NOTES – always use more than one criteria to gauge maturity

- 1 Soybean varieties have been organized into three maturity zones – short-, mid- and long-season areas. Although there are no variety restrictions, the **short-season** grouping is meant to be a starting point for new growers in the outer production areas. The **long-season** group is targeted for southern Manitoba generally south of highway 23, with the **mid-season** grouping making up the bulk of the production area between the short- and long-season area.
- 2 Company Crop Heat Unit ratings are assigned to assist growers in selecting varieties suitable for their area. Unfortunately Company Heat Unit ratings do not always reflect the actual maturity in Manitoba. Growers should never rely on just one criteria for judging maturity. Experimental lines are not assigned a HU rating until they become registered.
- 3 Relative days to maturity (DTM) is the number of days from seeding to plant maturity (95% of the pods on the plant are mature with seeds rattling in the pods when plant is shaken) and is expressed as + or - days from the check. The DTM have been calculated from four common sites (Portage, St. Adolphe, Morris) unless otherwise stated. Actual days to maturity for the check is found in the grey check box at the bottom of the table.

GENERAL NOTES

- 1 Roundup Ready, Conventional and soybean varieties are evaluated separately from Roundup Ready type varieties, meaning direct comparison of varieties between different tables is not possible. All trials are solid seeded at 210,000 plants/acre.
- 2 Hilum colour can range from Yellow (Y), Imperfect Yellow (IY), Grey (G), Brown (BR), Buff (BF) or Black (BL) and is solely a

marketing issue. The hilum is the point on the soybean seed where it attaches to the pod.

- 3 Relative Seeds/lb – these were the seed numbers of the varieties entered into the trial. Soybean seed size can vary greatly between varieties and even from seed lot to seed lot of the same variety. Growers should use the seed size for their seed lot when calculating seeding rates.
- 4 Lodging is rated at harvest; 1=standing upright, 5=flat along the ground. A rating of 3 or more can promote white mould within the crop canopy.
- 5 Iron Deficiency Chlorosis (IDC) rating scores 1=green leaves, 2=yellowish leaves, 3=green veins with yellow leaves, 4=brown dead tissue between green veins, 5=severe chlorosis and a stunted growing point. Ratings were taken from four sites prone to iron chlorosis over the last two years. IDC tolerant varieties are varieties with lower IDC scores and perform better on soils prone to iron deficiency chlorosis.
- 6 Iron Deficiency Chlorosis (IDC) grouping is used because varieties will have different visual rating scores from year to year. Numerical ratings, which are close but are in different groupings, will show similar symptoms. Both numerical and groupings should be considered together when judging IDC. Tolerant=leaves stayed green, Semi Tolerant=leaves when yellow then turned green, Susceptible=leaves went chlorotic and had dead patches on their leaves and were often stunted.
- 7 Soybeans are not eligible for MASC Production Insurance in all parts of the province – consult your local agent for more details.

CHECK CHARACTERISTICS

OAC Prudence	125	125	125	51	70	Y	2300	Normal	2.7
	days to maturity			bu/acre	site years		seeds/lb		

* Lodging rating averaged across Morris and Portage 2010 sites.

¹ On a whole seed content, Seed Protein in normal soybeans can range from 36% to 42%. Lower protein is usually an indication of poor nodulation during the growing season. Normal type soybeans (most Conventional and Roundup Ready soybeans grown in Manitoba) have a whole seed protein around 40%, mid-level types around 42.5% and high protein types around 45%.
